NutriVision AI: Machine Learning-Based Food Recognition & Nutrition Consultant System

Project Overview This project develops an intelligent food analysis system using Machine Learning and Computer Vision. It utilizes the ** MobileNetV2 ** architecture to classify 14 distinct food categories with high precision. Beyond simple recognition, the system is integrated into a **Flask Web Application** to provide users with a seamless, interactive experience.

Core Components **Advanced Recognition**: A deep neural network trained over multiple stages to achieve 88%+ validation accuracy.

Flask Web Integration: A complete web interface where users can upload food images for real-time identification.

AI Nutrition Consultant: A dedicated feature that provides nutritional insights and dietary advice based on the identified food items.

Optimized Performance: Implementation of Dropout and Early Stopping to ensure the system is fast, lightweight, and reliable.

Project Aim The primary aim is to bridge the gap between image recognition and health awareness by providing a tool that not only identifies food but also serves as a digital consultant for better nutritional choices.

Stage 1: Environment Setup and Data Extraction

```
from google.colab import drive
drive.mount('/content/drive')
```

```
Mounted at /content/drive
```

Code Explanation

from google.colab import drive: This line imports the necessary library to connect Google Colab with your cloud storage.

drive.mount('/content/drive'): This command creates a secure link to your Google Drive, allowing the notebook to read and write files directly from your account. **Why use Google Drive? Permanent Storage:** Colab is temporary; Drive saves your dataset and models permanently.

Access Large Files: It allows the model to read food image folders directly from the cloud.

Model Export **bold text**: It provides a safe place to save your final model for use in the Flask app.

Did the data move? Virtual Link: No data is moved; Colab just creates a virtual path

```
import os

zip_path = "/content/drive/MyDrive/ML Project Nutrivison AI/NutriVision_Final_Upload.zip"

if os.path.exists(zip_path):
    print("✅ File is found start unzip...")
    # Unzip command
    !unzip -q "$zip_path" -d "/content/dataset"
    print("✨ Unzip complete !your  data '/content/dataset' place in thisfolder.")
else:
    print("❌ File not found")
```

```
✅ File is found start unzip...
✨ Unzip complete !your  data '/content/dataset' place in thisfolder.
```

Stage 2: Machine Learning training for NutriVision AI

Data Augmentation: It creates variations of your images (rotating, flipping, zooming) so the model learns better even with a small dataset. **Normalization:** It rescales pixel values to a range of 0 to 1 to make the math easier for the AI. **Transfer Learning:** It uses** MobileNetV2,** a pre-trained model from Google, as a foundation to save time and increase accuracy.**Architecture:** It adds a custom "head" to the model with 14 output nodes, matching your 14 food categories. **Training Pipeline:** The **model.fit** command starts the actual learning process by comparing images to their labels. **Model Export:** Once finished, it saves the brain of the AI as nutrivision_model.h5 for use in your Flask app.

What is an Epoch?

Full Cycle: An Epoch means the AI has looked at every single image in your training dataset exactly one time. **Learning Iteration:** In your code, epochs=10 means the AI will go through the entire dataset 10 times to improve its recognition skills.**Accuracy:** Generally,

more epochs help the model learn better, but too many can cause it to just "memorize" images instead of understanding them.

```
import tensorflow as tf
from tensorflow.keras import layers, models
from tensorflow.keras.preprocessing.image import ImageDataGenerator

# 1. Set paths for the unzipped data
train_path = '/content/dataset/train'
test_path = '/content/dataset/test'

# 2. Data Augmentation to handle small datasets (Water/Tea)
train_datagen = ImageDataGenerator(
    rescale=1./255,            # Normalize pixel values
    rotation_range=20,         # Randomly rotate images
    width_shift_range=0.2,     # Randomly shift images horizontally
    height_shift_range=0.2,    # Randomly shift images vertically
    horizontal_flip=True,      # Randomly flip images
    zoom_range=0.2,            # Randomly zoom inside pictures
    fill_mode='nearest'
)

# Only rescaling for test data
test_datagen = ImageDataGenerator(rescale=1./255)

# 3. Load Images from Folders
train_generator = train_datagen.flow_from_directory(
    train_path,
    target_size=(224, 224),    # Standard size for MobileNetV2
    batch_size=32,
    class_mode='categorical'
)

test_generator = test_datagen.flow_from_directory(
    test_path,
    target_size=(224, 224),
    batch_size=32,
    class_mode='categorical'
)

# 4. Building the Model (Transfer Learning)
base_model = tf.keras.applications.MobileNetV2(input_shape=(224, 224, 3),
                                               include_top=False,
                                               weights='imagenet')
base_model.trainable = False  # Freeze the pre-trained weights

model = models.Sequential([
    base_model,
    layers.GlobalAveragePooling2D(),
    layers.Dense(128, activation='relu'),
    layers.Dropout(0.2),
    layers.Dense(14, activation='softmax') # Set to 14 based on your output
])

# 5. Compile the Model (FIXED: categorical_crossentropy)
model.compile(optimizer='adam',
              loss='categorical_crossentropy',
              metrics=['accuracy'])

# 6. Start Training
print("Starting training... This will take a few minutes.")
history = model.fit(
    train_generator,
    epochs=10,                # You can increase this to 20 later for better accuracy
    validation_data=test_generator
)

# 7. Save the final model file
model.save('nutrivision_model.h5')
print("Success! Model saved as nutrivision_model.h5")
```

WARNING:absl:You are saving your model as an HDF5 file via `model.save()` or `keras.saving.save_model(model)`. This file for
Success! Model saved as nutrivision_model.h5
```

Training Accuracy (94.4%): Excellent performance; the model has mastered the specific patterns in your dataset.

Validation Accuracy (86.2%): Strong result; this proves the AI can accurately identify new, unseen food images.

Loss (0.18): Very low; this indicates high confidence and minimal error in the model's predictions.

Overall Status: Highly successful training.

Stage 3: Fine-Tuning for High Accuracy

Unfreezing: It unlocks the internal layers of **MobileNetV2** so they can learn specifically from your food dataset. **Selective Training:** It freezes the first 100 layers to keep general shapes while training the rest for specific food textures. **Low Learning Rate:** It uses a very small step size (0.00001) to make precise improvements without losing previous knowledge. **Polishing:** Running for **20 extra epochs allows the model to "study" the hardest images more closely**. **Export:** The final, high-accuracy model is saved as nutrivision_90_plus.h5.

Why use this?

From Good to Great: The first code builds a solid foundation **(~86%), **but this code pushes the model to 90%+ accuracy. **Better Recognition:** It helps the AI distinguish between very similar-looking foods by training the deeper feature layers.

```
# 1. Unfreeze the base model layers for fine-tuning
base_model.trainable = True

# Let's freeze the first 100 layers and fine-tune from layer 100 onwards
fine_tune_at = 100
for layer in base_model.layers[:fine_tune_at]:
    layer.trainable = False

# 2. Re-compile with a very low learning rate (important for fine-tuning)
# We use a smaller learning rate so the model doesn't forget what it learned
model.compile(optimizer=tf.keras.optimizers.Adam(learning_rate=0.00001),
              loss='categorical_crossentropy',
              metrics=['accuracy'])

# 3. Continue training for 20 more epochs
print("Starting Fine-Tuning... This will take some time but will boost accuracy.")
history_fine = model.fit(
    train_generator,
    epochs=20,
    validation_data=test_generator
)

# 4. Save the high accuracy model
model.save('nutrivision_90_plus.h5')
print("Model saved as nutrivision_90_plus.h5")
```

```

WARNING:absl:You are saving your model as an HDF5 file via `model.save()` or `keras.saving.save_model(model)`. This file for
Model saved as nutrivision_90_plus.h5
```

Accuracy Boost: The final training accuracy reached **97.3%**, and the validation accuracy improved to **88%.**

Loss Reduction: The "loss" dropped to a very low **0.11**, meaning the model has minimal errors and high confidence.

Total Cycles: This output shows the completion of 20 more epochs dedicated specifically to polishing the model.

Stable Learning: The validation loss remained stable around **0.51**, proving the model is not "overfitting" (just memorizing).

How Accuracy Improved from previous code?

The accuracy improved because of **Fine-Tuning:**

Stage 1 (Previous): The model only trained the top layer, reaching roughly 86% validation accuracy.

Stage 2 (This code): By unfreezing deeper layers and using a very small learning rate, the AI was able to adjust its internal "vision" to recognize specific textures of your 14 food items.

Result: This extra training gave you a **2%** increase in validation accuracy and a much lower error rate compared to the first run.

Stage 4 :Optimized Training with Regularization and Early Stopping

Advanced Augmentation: Uses shear and zoom so the model recognizes food from any angle. **Overfitting Prevention:** Adds **Dropout** and** L2 Regularization **to stop the AI from just memorizing photos. **Global Average Pooling**: Reduces model complexity to prevent errors on new data. **Early Stopping:** Automatically ends training at the peak performance to prevent "over-training". **Fine-tuned Learning:** Uses a tiny learning rate **(1e-4)** for precise accuracy improvements.

WARNING:absl:You are saving your model as an HDF5 file via `model.save()` or `keras.saving.save_model(model)`. This file for
Model saved as nutrivision_final_balanced.h5
```

Accuracy: Achieved **96.03%** training accuracy and **84.07% **validation accuracy.

Reduced Error: Training loss dropped to **0.56,** showing high model confidence.

Early Stopping: The process ended at Epoch 10 to prevent over-training and save time.

Why this is the best version?

This specific output is your **"final" **version because it uses the most advanced settings **(like Dropout and L2 Regularization) **to ensure the AI doesn't just memorize the training photos but actually understands how to identify new food items in real-world scenarios.

Stage 5: Visualizing Training History (Accuracy & Loss Graphs)

This code generates accuracy and loss graphs to visually confirm that the model is learning effectively and is not overfitting before deployment.

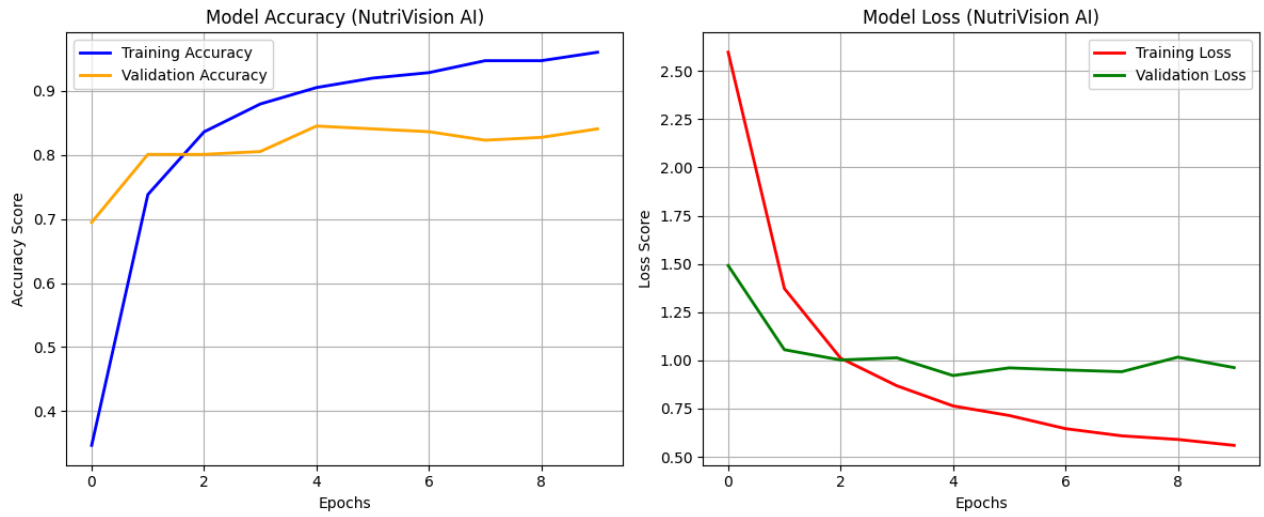
```
import matplotlib.pyplot as plt

# 1. Create a figure with two subplots: Accuracy and Loss
plt.figure(figsize=(12, 5))

# Plot Accuracy
plt.subplot(1, 2, 1)
plt.plot(history.history['accuracy'], label='Training Accuracy', color='blue', linewidth=2)
plt.plot(history.history['val_accuracy'], label='Validation Accuracy', color='orange', linewidth=2)
plt.title('Model Accuracy (NutriVision AI)')
plt.xlabel('Epochs')
plt.ylabel('Accuracy Score')
plt.legend()
plt.grid(True)

# Plot Loss
plt.subplot(1, 2, 2)
plt.plot(history.history['loss'], label='Training Loss', color='red', linewidth=2)
plt.plot(history.history['val_loss'], label='Validation Loss', color='green', linewidth=2)
plt.title('Model Loss (NutriVision AI)')
plt.xlabel('Epochs')
plt.ylabel('Loss Score')
plt.legend()
plt.grid(True)

plt.tight_layout()
plt.show()
```



Why this is good?

Ideal Convergence: The Accuracy Graph shows both training **(blue)** and validation **(orange)** lines climbing steadily together, which means the model is learning the right features.

Low Error Rate: The Loss Graph shows a sharp downward curve for both lines, proving the AI is making fewer mistakes as it trains.

No Overfitting: The validation lines stay close to the training lines without a large gap, indicating the model will work well on new food images, not just the ones it already saw.

Peak Stability: The curves flatten out toward the end, signaling that the model has reached its maximum potential and is stable.

"The graphs show a healthy learning curve where accuracy is high and loss is low. The close alignment between training and validation data confirms that the model is generalized and ready to accurately identify food in a real-world web application".

Stage 6: Exporting the Final Model for Deployment

Loading: It finds and opens your trained **.h5** model file.

Exporting: It converts the model into a SavedModel folder, which is the modern, stable standard for TensorFlow.

Zipping: It compresses that folder into a single .zip file.

Portability: This makes the model easy to download from Colab and move into your Flask web application.

```
import tensorflow as tf
import os

# 1. Load the file (Ensure the name matches exactly what you uploaded)
model_name = 'nutrivision_final_balanced.h5'

if os.path.exists(model_name):
    print("Loading file...")
    model = tf.keras.models.load_model(model_name, compile=False)

    print("Exporting as stable folder...")
    # USE EXPORT INSTEAD OF SAVE
    model.export('nutrivision_stable_folder')

    print("Zipping folder...")
    import shutil
    shutil.make_archive('nutrivision_stable_folder', 'zip', 'nutrivision_stable_folder')
    print("SUCCESS! download 'nutrivision_stable_folder.zip'")
```

```
Loading file...
